

gcmfaces

A Generic Treatment Of Gridded Earth Variables In Matlab

Gaël Forget
Department of Earth, Atmospheric and Planetary Sciences
Massachusetts Institute of Technology

January 2, 2017

Abstract

`gcmfaces` (Forget et al., 2015) is a `Matlab` toolbox that handles gridded earth variables in generic fashion so that compact analysis codes become applicable to a wide variety of grids (e.g., Fig. 1). `MITprof` (Forget et al., 2015) is a companion toolbox for handling unevenly distributed in-situ observations. This note provides an installation guide for both toolboxes (section 1), a documentation of basic `gcmfaces` features (sections 2), and user guidance regarding higher-level `gcmfaces` functionalities such as mapping and transport computations (sections 3 and 4).

Figure 1: Four approaches to gridding the Earth which are all commonly used in numerical models. Top left: lat-lon grid; mapping the Earth to a single rectangular array ('face'). Top right: cube-sphere grid; mapping the earth to the six faces of a cube. Bottom right: lat-lon-cap, 'LLC', grid (five faces). Bottom left: quadripolar grid (four faces). In this depiction, faces are color-coded, only grid line subsets are shown, and gaps are introduced between faces to highlight the defining characteristics of each grid.

1 Install And Get Started

2 1.1 Software Installation

3 The recommended approach consists in downloading the latest `gcmfaces` and `MITprof` software
4 version from github via <https://github.com/gaelforget>. The code can be downloaded either via
5 a web-browser by using the github interface or via the command line by typing:

```
6 git clone https://github.com/gaelforget/gcmfaces  
7 git clone https://github.com/gaelforget/MITprof
```

8 It can later be updated, e.g., by typing `git pull` at the command line.

9 Alternatively, if needed, earlier versions of the code can be downloaded directly from
10 [c66b_gcmfaces.tar](#) and [c66b_MITprof.tar](#) or via the `MITgcm` CVS server where the initial devel-
11 opment phase, through 2016, is documented. In the latter case, one logs into the `MITgcm` CVS
12 server as explained @ http://mitgcm.org/public/using_cvs.html and then types:

```
13 cvs co -P -r checkpoint66b -d gcmfaces MITgcm_contrib/gael/matlab_class  
14 cvs co -P -r checkpoint66b -d MITprof MITgcm_contrib/gael/profilesMatlabProcessing
```

15 1.2 Data Downloads

16 To get started (sections 1.3 and 2) one downloads the LLC90 grid (`'nctiles_grid/'`; 145M) either
17 from the [MIT ftp server](#) or from its [Dataverse permanent archive](#). To illustrate higher-level func-
18 tions, sections 3 and 4 rely on the ECCO v4 r2 ocean state estimate (Forget et al., 2016) directo-
19 rories as shown in Fig. 2. The relevant files can be downloaded from the [Dataverse permanent archive](#)
20 or from the [MIT ftp server](#), e.g., using commands reported in Fig. 3.

21 Downloading `'nctiles_climatology/'` (10G), `'nctiles_grid/'` (145M), and the `Matlab` code (`gcmfaces`,
22 `MITprof`, and `m_map`) suffices for the basic purposes of section 3 and 4. The files in `'profiles/'` (7G)
23 and `'nctiles_remotesensing/'` (27G) allow for model-data comparisons. The `'nctiles_monthly/'` di-
24 rectory contains the full 1992-2011 ECCO v4 r2 monthly time series (170G) and can be used to
25 reproduce the Forget et al. (2016) plots as explained in section 4.

26 1.3 Get Started

27 Once `'gcmfaces/'`, `'MITprof/'`, and `'nctiles_grid/'` have been placed in a common directory (`'./'`
28 in Fig. 2), one may simply open `Matlab` from that directory and type:

```
29 %add gcmfaces and MITprof directories to Matlab path:  
30 p = genpath('gcmfaces/'); addpath(p);  
31 p = genpath('MITprof/'); addpath(p);  
32  
33 %load all grid variables from nctiles_grid/ into mygrid:  
34 grid_load;  
35  
36 %make mygrid accessible in current workspace:  
37 gcmfaces_global;  
38
```

```

39 %display list of grid variables:
40 disp(mygrid);
41
42 %display one gcmfaces variable:
43 disp(mygrid.XC);
44

```

Figure 2: Directory structure that allows users to execute Matlab code snippets provided in this user guide. The basic `gcmfaces` installation only requires the `gcmfaces/`, `MITprof/`, and `nctiles_grid/` directories (see section 1 for details). The `m_map` toolbox that `gcmfaces` relies on for geographic projections is available at <https://www.eoas.ubc.ca/~rich/map.html>. The `release2_climatology/`, and `release2/` directories serve to demonstrate higher-level functions in sections 3 and 4.

```

./

wget --recursive ${FTPv4r2}/nctiles_remotesensing
wget --recursive ${FTPv4r2}/profiles

```

45 2 The Basic gcmfaces Features

46 The core of `gcmfaces` lies in its handling of connected arrays/faces via a new `Matlab` class/variable
47 type (section 2.1) and its handling of C-Grid specifications via the `mygrid` global variable (sec-
48 tion 2.2). Basic features of `gcmfaces` also include functions that ‘exchange’ data between faces
49 (section 2.3), ‘overloaded’ operations (section 2.4), and I/O functions (section 2.5). `gcmfaces`
50 functions are normally documented via help sections that are accessible within `Matlab`.

51 2.1 The gcmfaces Class

52 Fig. 1 illustrates four types of grids that are commonly used in general circulation models
53 (GCMs). Despite evident design differences, these grids can all be represented as sets of con-
54 nected arrays (‘faces’) as illustrated in Fig. 4 for the LLC90 grid. `gcmfaces` simply takes
55 advantage of this fact by defining an additional `Matlab` class, within `@gcmfaces/`, to represent
56 gridded earth variables generically as sets of connected arrays.

57 Grid specifics, such as the number of faces and grid points, are embedded within `gcmfaces`
58 objects as illustrated in Table 1. Objects of the `gcmfaces` class can thus be manipulated simply
59 through compact and generic expressions such as ‘a+b’ that are robust to changes in grid design
60 (Fig. 1). The `gcmfaces` class inherits many of its basic operations (see section 2.4 for details)
61 from the ‘double’ class as illustrated in Table 2 for `@gcmfaces/plus.m`.

Table 1: Earth variable on the LLC90 grid (Fig. 1, bottom right) represented as an object of the `gcmfaces` class (`@gcmfaces/`). The five face arrays (going from f1 to f5) are depicted in Fig. 4 accordingly.

fId =
nFaces: 5
f1: [90x270 double]
f2: [90x270 double]
f3: [90x90 double]
f4: [270x90 double]
f5: [270x90 double]

62 2.2 C-Grid Variables

63 In practice the `gcmfaces` framework gets activated by adding, to the least, the `@gcmfaces/` direc-
64 tory to the `Matlab` path and then loading a grid to memory as done in section 1.3. The default,
65 LLC90, grid can be loaded to memory by calling `grid_load.m` without any argument. ‘help
66 `grid_load.m`’ and section 2.5 provide additional information regarding, respectively `grid_load.m`
67 arguments and supported file formats. Alternatively, grids can be read from MITgcm input files
68 using `grid_load_native.m` as shown in [this webpage](#) (see `README` and `demo_grids.m`).

69 `grid_load.m` and `grid_load_native.m` store all C-grid variables at once in a global variable
70 named `mygrid` (Tab. 3). `gcmfaces` functions often rely on `mygrid` that they access via a call to
71 `gcmfaces_global.m` which also provides system information via `myenv`. If these global variables

Table 2: The '+' operation as defined for `gcmfaces` objects by `@gcmfaces/plus.m`. In executing commands such as 'a+b', Matlab will use `@gcmfaces/plus.m` if either 'a' or 'b' is of the `gcmfaces` class.

```
function r = plus(p,q)
%overloaded gcmfaces '+' function :
% simply calls double '+' function for each face data
% if any of the two arguments is a gcmfaces object

if isa(p,'gcmfaces'); r=p; else; r=q; end;
for iFace=1:r.nFaces;
    iF=num2str(iFace);
    if isa(p,'gcmfaces')&isa(q,'gcmfaces');
        eval(['r.f' iF '=p.f' iF '+q.f' iF ';'']);
    elseif isa(p,'gcmfaces')&isa(q,'double');
        eval(['r.f' iF '=p.f' iF '+q;']);
    elseif isa(p,'double')&isa(q,'gcmfaces');
        eval(['r.f' iF '=p+q.f' iF ';'']);
    else;
        error('gcmfaces plus: types are incompatible')
    end;
end;
```

72 get deleted, typically by a ‘clear all’, then another call to `grid_load.m` is generally needed.
 73 `gcmfaces_global.m` will indicate this situation to the user by issuing warnings that ‘mygrid has
 74 not yet been loaded to memory’.

Table 3: List of grid variables available via the `mygrid` global variable. The naming convention is directly inherited from the MITgcm naming convention. For details, see sections 2.11 and 6.2.4 in http://mitgcm.org/public/r2_manual/latest/online_documents/manual.pdf

XC	: [1x1 gcmfaces]	longitude (tracer)
YC	: [1x1 gcmfaces]	latitude (tracer)
RC	: [50x1 double]	depth (tracer)
XG	: [1x1 gcmfaces]	longitude (vorticity)
YG	: [1x1 gcmfaces]	latitude (vorticity)
RF	: [51x1 double]	depth (velocity along 3rd dim)
DXC	: [1x1 gcmfaces]	grid spacing (tracer, 1st dim)
DYC	: [1x1 gcmfaces]	grid spacing (tracer, 2nd dim)
DRC	: [50x1 double]	grid spacing (tracer, 3rd dim)
RAC	: [1x1 gcmfaces]	grid cell area (tracer)
DXG	: [1x1 gcmfaces]	grid spacing (vorticity, 1st dim)
DYG	: [1x1 gcmfaces]	grid spacing (vorticity, 2nd dim)
DRF	: [50x1 double]	grid spacing (velocity, 3rd dim)
RAZ	: [1x1 gcmfaces]	grid cell area (vorticity)
AngleCS	: [1x1 gcmfaces]	grid orientation (tracer, cosine)
AngleSN	: [1x1 gcmfaces]	grid orientation (tracer, cosine)
Depth	: [1x1 gcmfaces]	ocean bottom depth (tracer)
hFacC	: [1x1 gcmfaces]	partial cell factor (tracer)
hFacS	: [1x1 gcmfaces]	partial cell factor (velocity, 2nd dim)
hFacW	: [1x1 gcmfaces]	partial cell factor (velocity, 1rst dim)

75 The C-grid variable names listed in Tab. 3 derive from the MITgcm¹. In brief, XC, YC,
 76 and RC denote longitude, latitude, and vertical position of tracer variable locations. DXC,
 77 DYC, DRC and RAC are the corresponding grid spacings, in m, and grid cell areas, in m². A
 78 different set of such variables (XG, YG, RF, DXG, DYG, DRF, RAZ) corresponds to velocity
 79 and vorticity variables that are staggered in a C-grid approach¹.

80 Indexing and vector orientation conventions also derive from the MITgcm¹. The indexing
 81 convention is illustrated in Fig. 4. For vector fields, the first component (U) is directed toward
 82 the right of the page and the second component (V) toward the top of the page. As compared
 83 with tracers, velocity variable locations are shifted by half a grid point to the left of the page
 84 (U components) or the bottom of the page (V components) following the C-grid approach¹.

85 2.3 Exchange Functions

86 Many computations of interest (e.g., gradients and flow convergences) involve values from con-
 87 tiguous grid points on neighboring faces. In practice rows and columns need to be appended at

¹For details, see sections 2.11 and 6.2.4 in http://mitgcm.org/public/r2_manual/latest/online_documents/manual.pdf

88 each face edge that are ‘exchanged’ between neighboring faces – e.g., rows and columns from
89 faces #2, #3, and #5 at the face #1 edges in Fig. 4. Exchanges are operated by `exch_T_N.m` for
90 tracer-type variables and by `exch_UV_N.m` for velocity-type variables. They are used to compute
91 gradients (`calc_T_grad.m` and flow convergences (`calc_UV_conv.m`) in sections 3 and 4.

92 2.4 Overloaded Functions

93 As illustrated for the ‘+’ operation in Table 2, common functions are overloaded as part of the
94 `gcmfaces` class definition within the `@gcmfaces/` directory:

- 95 1. Logical operators: `and`, `eq`, `ge`, `gt`, `isnan`, `le`, `lt`, `ne`, `not`, `or`.
- 96 2. Numerical operators: `abs`, `angle`, `cat`, `cos`, `cumsum`, `diff`, `exp`, `imag`, `log2`, `max`,
97 `mean`, `median`, `min`, `minus`, `mrdivide`, `mtimes`, `nanmax`, `nanmean`, `nanmedian`, `nanmin`,
98 `nanstd`, `nansum`, `plus`, `power`, `rdivide`, `real`, `sin`, `sqrt`, `std`, `sum`, `tan`, `times`,
99 `uminus`, `uplus`.
- 100 3. Indexing operators: `subsasgn`, `subsref`, `find`, `get`, `set`, `squeeze`, `repmat`.

101 It may be worth highlighting `@gcmfaces/subsasgn.m` (subscripted assignment) and
102 `@gcmfaces/subsref.m` (subscripted reference) since they overload some of the most commonly
103 used `Matlab` functions. For example, if `fld` is of the ‘double’ class then ‘`tmp2=fld(1);`’ and
104 ‘`fld(1)=1;`’ call `subsref.m` and `subsasgn.m`, respectively. If `fld` instead is of the `gcmfaces` class
105 then `@gcmfaces/subsref.m` behaves as follows:

106 `fld{n}` returns the n^{th} face data (i.e., an array).
107 `fld(:, :, n)` returns the n^{th} vertical level (i.e., a `gcmfaces` object).

108 and `@gcmfaces/subsasgn.m` behaves similarly but for assignments.

109 2.5 I/O Functions

110 Objects of the `gcmfaces` class can readily be saved to file using `Matlab`’s proprietary I/O format
111 (‘.mat’ files). Reloading them in a later `Matlab` session works seamlessly as long as the `gcmfaces`
112 class has been defined by including `@gcmfaces/` in the `Matlab` path.

113 Alternatively, `gcmfaces` variables can be written to files in the ‘nctiles’ format (Forget et al.,
114 2015). Illustrations in this user guide rely upon ECCO v4 fields which are distributed in
115 this format (see section 1.2; Figs. 2-3). The I/O functions provided as part of `gcmfaces`
116 (`write2nctiles.m` and `read_nctiles.m`) reformat data on the fly.

117 `gcmfaces` can also read MITgcm binary output in the ‘mds’ format². The provided I/O
118 functions (`rdmds2gcmfaces.m` and `read_bin.m`) rely on `convert2gcmfaces.m` to reformat data
119 on the fly. `gcmfaces` thus readily provides a common tool to analyze any of the [ECCO solutions](#)
120 as illustrated in [this webpage](#) (see `README` and `demo_grids.m`).

²For details, see section 7.3 in http://mitgcm.org/public/r2-manual/latest/online_documents/manual.pdf

121 3 The gcmfaces_demo.m Tutorial

122 To proceed further, user should have completed the installation procedure in section 1.3 including
123 for nctiles_climatology/ and m_map/. To illustrate gcmfaces capabilities, gcmfaces_demo.m
124 can then be executed by opening Matlab and typing

```
125 p = genpath('gcmfaces/'); addpath(p);  
126 p = genpath('m_map/'); addpath(p);  
127 gcmfaces_demo;
```

128 As prompted by gcmfaces_demo.m, users specify the desired amount of explanatory text
129 output. gcmfaces_demo.m then proceeds various the examples while displaying comments
130 in the Matlab command window. The Matlab GUI and debugger can also be used to run the
131 examples line by line to learn more about the inner workings of gcmfaces functions.

132 The first section in gcmfaces_demo.m illustrates I/O and plotting capabilities (grid_load.m
133 and example_display.m). gcmfaces relies on m_map) for map projections via the m_map_gcmfaces
134 front-end that typically produces Fig. 5. The second section in gcmfaces_demo.m focuses on data
135 processing capabilities such as interpolation (example_interp.m) and smoothing (example_smooth.m).
136 example_interp.m interpolates gcmfaces fields to a lat-lon grid and vice versa. example_smooth.m
137 integrates a diffusion equation which involves tracer gradient and flux convergence computations.
138 The final section in gcmfaces_demo.m computes oceanic transports (example_transports.m).

139 4 The gcmfaces_diags/ Standard Analysis

140 The gcmfaces ‘standard analysis’ consists of an extensive set of physical diagnostics that are
141 routinely computed to monitor and compare MITgcm simulations and ECCO state estimates
142 (e.g., Forget et al., 2015, 2016). The computational loop is operated by diags_driver.m which
143 expects stores results in a dedicated directory (mat/ in Fig. 2). Afterwards, the display phase
144 is normally carried out via diags_display.m or diags_driver_tex.m as explained below.

145 At this point, users should have completed the installation procedure in section 1.3 including
146 for nctiles_climatology/ and m_map/ and organized directories as shown in Fig. 2. They can
147 then generate and display variance maps (setDiags='B' encoded in diags_set_B.m) from the
148 ECCO v4 monthly mean climatology (12 monthly fields) by opening Matlab and typing:

```
149 %add paths:  
150 p = genpath('gcmfaces/'); addpath(p);  
151 p = genpath('MITprof/'); addpath(p);  
152 p = genpath('m_map/'); addpath(p);  
153  
154 %set parameters:  
155 dirModel='release2_climatology/';  
156 dirMat=[dirModel 'mat/'];  
157 setDiags='B';  
158  
159 %compute diagnostics:  
160 diags_driver(dirModel,dirMat,'climatology',setDiags);
```

```
161
162 %display results:
163 diags_display(dirMat,setDiags);
```

164 which takes ≈ 5 minutes. Each generated plot has a caption that indicates the quantity being
165 displayed. Results of `diags_driver.m` can, alternatively, be displayed via `diags_driver_tex.m`
166 to save plots and create a compilable tex file. This process takes ≈ 10 minutes:

```
167 dirTex=[dirModel 'tex/']; nameTex='standardAnalysis';
168 diags_driver_tex(dirMat,{},dirTex,nameTex);
```

169 Other diagnostic sets can be computed and displayed accordingly by modifying the ‘setDiags’
170 specification: oceanic transports (‘A’), mean and variance maps (‘B’), sections and time series
171 (‘C’), and mixed layer depths (‘MLD’). Each set of diagnostics (computation and display) is
172 encoded in one routine named as ‘diags_set_XX.m’ where ‘XX’ stands for e.g., ‘A’, ‘B’, ‘C’, or
173 ‘MLD’. These routines can be found in the `gcmfaces_diags/` subdirectory.

174 Computing these four diagnostic sets from ECCO v4 r2 climatology takes $\approx 1/2$ hour. Com-
175 puting them from the 1992-2011 monthly time series (`nctiles_monthly/` in Fig. 2) per

```
176 dirModel='release2/'; dirMat=[dirModel 'mat/'];
177 diags_driver(dirModel,dirMat,[1992:2011]);
```

178 takes ≈ 20 times longer and typically runs overnight. However, to speed up the process, com-
179 putation can be distributed over multiple processors by splitting [1992:2011] into subsets.
